THE TOW BGM-71E MISSILE

Antitank missiles work by piercing the armor and killing the crew, or by disabling vital mechanical systems inside the vehicle. Reactive armor responds to the impact of a missile to reduce the damage to the vehicle. The BGM-71E was developed for the U.S. Army specifically to defeat reactive armor.

THE M220 LAUNCHER

One method of faunching the missile is a tripod-mounted launcher now in use by Syrian rebel groups. The missiles can be fired by a single operator but require a team of four to move the launch tube supporting equipment from place to place.

THE MISSILE LAUNCH SEQUENCE

- The initial launch engine burns for less than half a second. It shuts down before the missile leaves the tube.
- 2. Front wings unfold as the missile leaves the launcher.
- The unfolding wings close a circuit that site ignites the second flight motor about 25 feet from the launcher.
- Control surface fins unfold immediately after launch and respond to signals through a command-wire link.
- Wire dispensers in the rear of the missile spool out up to 12,000 feet of single-strand command wire.
- A xenon beacon and a thermal beacon in the rear of the missile is detected by the thermal tracker in the telescopic sight unit (TSU).
